Disclaimer

Proper installation and servicing of the Total Green Mfg. heat pump is essential to its reliable performance. All Total Green Mfg. systems must be installed and serviced by a qualified HVAC contractor. Equipment sizing, selection and installation are the sole responsibility of the installing contractor.

Installations of equipment on an existing copper earth loop design that does not match a current Total Green Mfg. earth loop design is not permitted, will void all warranties on the equipment, and is the sole responsibility of the installing contractor. Installation must be made in accordance with the instructions set forth in this manual. Failure to provide installation by a qualified HVAC contractor in a manner consistent with this manual will void and nullify the limited warranty coverage for the system.

Total Green Mfg. shall not be liable for any defect, unsatisfactory performance, damage or loss, whether direct or consequential, relative to the design, manufacture, construction, application or installation of any field specified components.

Sizing for DX Systems (Refrigerant to Forced Air)

Note: Proper sizing is critical to the performance, efficiency and reliability of Total Green Mfg. Waterless Geothermal® systems.

In addition to the information found in the most recent Total Green Mfg. equipment manuals, the following steps are to be used for selecting a Total Green Mfg. Waterless Geothermal® system.

Step 1: Perform a Load Calculation Determine heating and cooling requirements of the structure based on an ACCA approved load calculation (Latest Edition) using the unabridged ASHRAE 99% outdoor heating design temperature and the 1% outdoor cooling design temperatures for your location. These tables are included at the end of this manual. Refer to pages 7, 8 and 9 for information to assist in performing a proper load calculation for Total Green Mfg. Waterless Geothermal® systems.

Why the Unabridged 99/1% ASHRAE Table Must Be Used: *Using the unabridged ASHRAE 99% and 1% tables are critical to sizing for the proper function and cycling of the Waterless Geothermal® system. These are the same tables used by Energy Star for Energy Star compliant homes. Using these tables will greatly reduce the use of auxiliary heat and reduces run times in cooling mode. Unlike conventional air to air systems or, other geothermal equipment brands, Waterless Geothermal® systems have a higher and more constant latent cooling capacity. Long extended run times in cooling for dehumidification are not needed nor wanted. This greater latent capacity allows sizing to meet heating loads in those heating dominate climates without the limitations on cooling associated with other heat pump and geothermal equipment brands. If necessary, changing the outdoor design temperature defaults to match the unabridged 99% & 1% ASHRAE table in some load calculation software is imperative. The outdoor design temperatures given in these tables are the maximum for heating and the minimum for cooling. The outdoor heating temperature can be lowered but never raised, and the outdoor cooling temperature may be raised but never lowered.*

Step 2: Determine the Dominate Load Determine from the manual “J” section of your load calculation where the most system capacity in BTU is required. If more BTU’s are required for heating (Heating Dominant), use the heating load to select your equipment size. If more BTU’s are needed for cooling (Cooling Dominant) use the cooling load to select your equipment size. You must choose equipment that meets or slightly exceeds the dominate load requirement. Never undersize.

Required Adder for 100% Hot Water Option *If an “M” series model WG2AD, 100% domestic water heating is to be used, an additional 6,000 BTU’s must be added to your dominate load requirement, rather the dominant load be heating or cooling. Domestic water heating adds load to the equipment and must be accounted for.*

STEP 3: Determine if 2 Stage equipment is required *Total Green Waterless Geothermal® systems can be sized up to 150% of your total cooling load for single stage equipment while meeting 100% of your heating load. However, it is required that when the heating load exceeds 1.5 times (150%) the total cooling load, that two stage equipment be utilized. To figure this, simply divide the heating load BTU requirement by the total cooling load BTU requirement. If the answer is 1.5 (150%) or less, single stage equipment would be acceptable. However, if the answer is greater than*

1.5 (150%), two stage equipment would be required so no issues of equipment short cycling or dehumidification occur.

Example: You have a heating load requiring 49,542 BTUH of system capacity and, a total cooling load requiring 29,362 BTUH of system capacity. $49,542 \div 29,362 = 1.68$. This is 1.68 times (168%) greater than your heating load. In this example, since 168% is greater than 150% of the heating load, two stage equipment would be required.

Step 4: Review Air Flow Requirements Review the air flow (CFM) section of your load calculation. As building construction and insulation materials improve, heat loss and heat gain values may be significantly less than the required air flow. Keep in mind, a Waterless Geothermal® system requires 400 CFM of air flow per unit ton for proper operation. It may be necessary to up size equipment when air flow requirements are significantly higher than what can be provided at 400 CFM per unit ton. Keep in mind, you must have proper air flow and air exchanges to condition a space. We recommend up sizing the equipment so as to be able to provide at least 75% of the load calculation air flow requirement.

Example: The total cooling load (heat gain) is 36,000 BTUH which is 3 tons of equipment. The load calculation air flow requirement calculated in the load is 2,000 CFM. Keep in mind that if a 3 ton unit is selected based on heat gain alone, you only have 1,200 CFM (400 CFM per ton) which is 800 CFM short. In this example we would use a multiplier of .75 for the 2,000 CFM given in the load calculation. $2,000 \times .75 = 1,500$ CFM. In this example, you will want to select a 4 ton unit giving you 1,600 CFM.

Step 5: Choosing Unit Model Select the Waterless Geothermal® system size based on the compressor unit model number. The size selected should be equal to or, greater than the dominate portion of your load calculation, never under. For example; a WGxA-60xx would be a 5 ton unit or, 60,000 BTUH. The “60” represents the system design nominal capacity for both heating and cooling. Other examples, a WGxA-24xx would be a 2 ton machine or, 24,000 BTUH, a WGxA-36xx would be a 3 ton machine or, 36,000 BTUH and so on. Please refer to the nomenclature on page 5 for each unit’s nominal capacity rating. The nominal capacity listed covers both heating and/or cooling capacities.

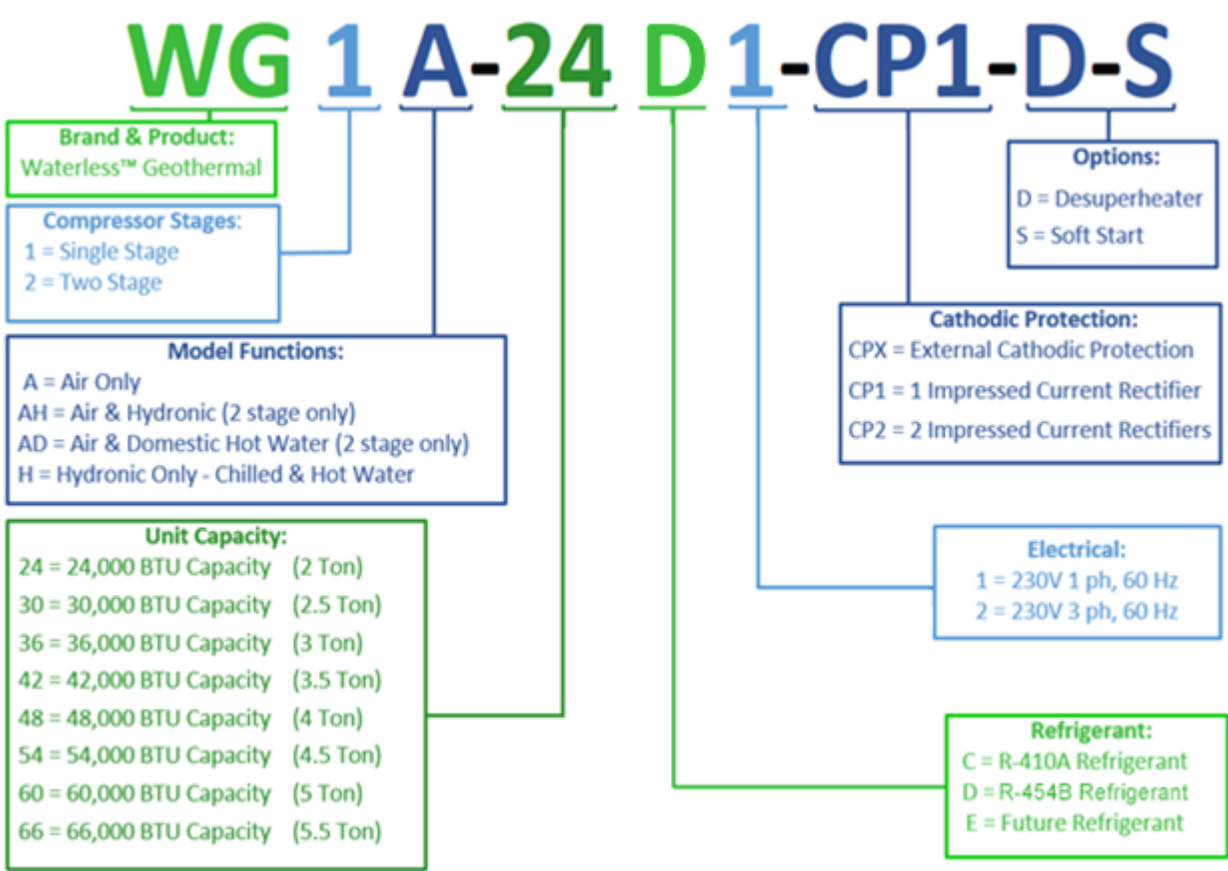

Step 6: Sizing Auxiliary Heat System Auxiliary heat is required with all Waterless Geothermal® systems. Rather it be electric back up in the air handler or, a gas furnace as a dual fuel application. If electric heat in the air handler is used, the heat kit should be sized for at least 50% of the Waterless Geothermal® system’s heating capacity. Each 5KW of heat strip has an average output of 17,000 BTUH.

Staging Auxiliary Heat: Proper staging of auxiliary is extremely critical. Staging auxiliary heat should never be done by differential temperature alone. I.E. waiting until the system doesn’t maintain thermostat set point. Auxiliary heat should be staged when the system capacity is at 90% of the load. This is within 10% of the balance point. Balance point is when the outdoor temperature drops to the point where the heat loss equals the equipment capacity which, equals 100% run time. 100% run time is detrimental to Waterless Geothermal® equipment. Resting periods, I.E. a maximum of a 90% duty cycle should not be exceeded so as to provide resting periods for the earth loop field to recover heat. This allows the unit to maintain peak efficiency and capacity. Staging of auxiliary heat can be done most effectively by using a thermostat that allows staging based on run time. A properly sized system should be able to maintain the thermostat set point within 20 minutes of run time. If run time exceeds 20 minutes, then the load balance point is nearing. Set your auxiliary heat stage timer to 20 minutes.

An Alternative method to staging auxiliary can be done more accurately with some thermostat brands such as the Honeywell Pro line series, which will calculate auxiliary heat staging when the equipment is at 90% capacity. This is based on run time data stored and calculated in the thermostat’s logic. If this method is desired, be sure the thermostat used offers this feature and make sure it is enabled.

Another method is to calculate the building Balance point and use an outdoor thermostat to stage auxiliary heat. With this method, the auxiliary heat will turn on with the equipment when the set temperature of the outdoor thermostat is reached. Just be sure the balance point temperature setting is figured within 90% of the outdoor design temperature. For assistance with balance point calculations, contact Total Green Technical Support.

Compressor Unit Nomenclature

Considerations for Hydronic Heated and Chilled Water systems

Step 1: Perform a Load Calculation Determine heating and cooling requirements of the structure based on ACCA approved load calculation (latest Edition) using the unabridged ASHRAE 99% outdoor heating design temperature and the 1% outdoor cooling design temperatures for your location. These tables are included at the end of this manual. If your location is not listed, use the nearest listed location.

Why the Unabridged 99/1% ASHRAE Table Must Be Used: *Using the unabridged ASHRAE 99% and 1% tables are critical to sizing for the proper function and cycling of the Waterless Geothermal® system. These are the same tables used by Energy Star for Energy Star compliant homes. Using these tables will greatly reduce the use of auxiliary heat and reduces run times in cooling mode. Unlike conventional air to air systems or, other geothermal equipment brands, Waterless Geothermal® systems have a higher and more constant latent cooling capacity. Long extended run times in cooling for dehumidification are not needed nor wanted. This greater latent capacity allows sizing to meet heating loads in those heating dominate climates without the limitations on cooling associated with other heat pump and geothermal equipment brands. **If necessary, changing the outdoor design temperature defaults to match the unabridged 99% & 1% ASHRAE table in some load calculation software is imperative. The outdoor design temperatures given in these tables are the maximum for heating and the minimum for cooling. The outdoor heating temperature can be lowered but never raised, and the outdoor cooling temperature may be raised but never lowered.***

Step 2: Determine Distribution Requirements Determine the BTU requirements for each area and design your radiant floor heating system and/or hydronic air handlers to deliver the required BTU's needed for each area/zone. To achieve maximum system efficiencies, it is recommended to design a hydronic system for 100° F water temperatures or less for heated water and, 45° F or higher for chilled water. The absolute minimum and maximum design temperatures for a hydronic distribution system (radiant floor or hydronic air handlers) can be designed using a maximum heated water temperature of 110° F and a minimum chilled water temperature of 42° F. Higher water temperatures for heating when needed, such as approaching balance point temperatures, would require an additional heat source. Read the "Hot Water Auxiliary Heat Requirements" section near the end of this page.

Step 3: Calculating the Distribution Requirements Add up the BTU's your distribution system is designed to deliver to each area/zone for both heating and cooling. Using the greater of these two values, select a hydronic unit with at least 10% greater capacity than what the distribution system delivers. This extra capacity is to account for pumping and piping losses.

Example: *Your hydronic distribution system as designed based on the given water temperatures from "Step 2", needs to deliver 35,265 BTUH for cooling and 47,520 BTUH for heating. Since heating is the dominate load, use that value plus 10%. $47,520 \times 1.10 = 52,272$ BTUH. You must select a unit to deliver at least 52,272 BTUH. In this example, a 4.5 ton unit (WG1H-54xx) would be needed at 54,000 BTUH of nominal capacity. The same formula will apply for dominate cooling loads as well.*

Auxiliary Heat Requirements: Auxiliary heat is required of all Waterless Geothermal® systems. In the case of hydronic distribution, auxiliary heat is figured by the output capacity of the distribution system and zones, not the compressor unit capacity as you would with refrigerant to air systems. Knowing this difference is important. If

hydronic air handlers are used, standard heat kits can be used in the air handlers. If hydronic radiant floor is used, a method of raising the water temperature for more capacity when needed, such as electric elements in the buffer tank or, a modulating boiler should be considered. For auxiliary heat staging considerations, please refer to page 4.

Please contact Total Green Mfg. at 419-678-2032 with any question regarding these sizing procedures. Along with proper installation of the equipment per Total Green Mfg. installation manuals, sizing is a critical step necessary for an efficient and reliable system.

Load Calculation Do's and Don'ts for Total Green's Direct Exchange Waterless Geothermal®

Disclaimer

Proper installation and servicing of the Total Green Mfg. heat pump is essential to its reliable performance. All Total Green Mfg. systems must be installed and serviced by a qualified HVAC contractor. Equipment sizing, selection and installation are the sole responsibility of the installing contractor.

The following information is applied only to Waterless Geothermal® equipment and may be contradictive to industry standards for conventional and other geothermal systems. Waterless Geothermal® equipment is unique in design and function. Failure to follow these guidelines along with the information provided in Total Green's "System Sizing and Selection" manual or, following standards for conventional or other geothermal equipment may be detrimental to the proper operation of Waterless Geothermal® equipment.

Introduction: Direct Exchange Geothermal systems although similar with respect to sizing of other HVAC equipment, considerations must be given for the proper function of a Direct Exchange Geothermal. Unlike conventional air to air systems or, other geothermal equipment brands, our Direct Exchange Waterless Geothermal® brand of equipment has a higher and more constant latent cooling capacity. Long extended run times in cooling for dehumidification are not needed nor wanted. This greater latent capacity allows sizing to meet heating loads in those heating dominate climates without the limitations on cooling associated with other heat pump and geothermal equipment brands. In addition, sizing the equipment properly as per the information provided in Total Green's "System Sizing and Selection" manual, provides the required duty cycle (resting periods) for the earth loop field to regain or dissipate heat between calls so the field maintains peak performance. This is especially true for cooling as, unlike heating which can be supplemented with an auxiliary heat source, auxiliary cooling does not exist. This all starts with a proper load calculation.

Load Calculation Do's (Mandatory Requirements)

1. Do use the unabridged 99/1% ASHRAE Table for the outdoor design temperatures:

These tables are provided for you in the "System Sizing and Selection" manual. Using the unabridged ASHRAE 99% and 1% tables are critical to sizing for the proper function and cycling of the Waterless Geothermal® system.

2. Do room by room calculations, not block loads:

Room by room load calculations provides a more detailed load and air flow requirement for each room as well as an overall more accurate load analysis for the entire building.

3. Additional load values:

It is also recommended that additional load values be added to certain rooms for a typical residential application as follows;

Kitchens with standard appliances and exhaust fans add 1,200 BTUH sensible and 1,200 BTUH Latent.

Laundry Rooms add 600 BTUH sensible and 600 BTUH Latent.

Bath/Powder Room Exhaust Fans. These are typically 80 CFM but are not ran on a continuous bases so, adding 20 CFM of exhaust for each should be accounted for and is sufficient.

Please note; Kitchen appliances outside the normal, oversized exhaust fans or, any other excessive heat generating devices anywhere in the home should be considered on a case by case bases.

4. Occupancy: Occupancy must be factored in. Simply count occupancy as two persons per bedroom, even if that bedroom is not in use. Not considering each bedroom as occupied by two persons could lead to comfort issues, especially in the cooling season when those unused bedrooms may be occupied by guests. Adding additional people beyond two per bedroom anywhere else under normal living conditions is not necessary.

5. Construction Details:

- A. Verify all construction details prior to performing Load Calculations. Having the correct insulation values will greatly reduce the chances of under sizing for heating or, grossly over sizing for cooling.
- B. Consider the orientation of each side of the structure on the site. The Orientation has impact on system zoning. Taking the direction (North, South, East, West) that each side of the structure faces into consideration ensures that the correct conditioned airflow will be delivered to each room.
- C. Verify Insulation values as specified for new construction or as installed for existing construction.
- D. Be critical of the envelope tightness. Typically older homes would be on the loose side with regards infiltration whereas newer spec-built homes will have an average or slightly better tightness. Never figure a home as very tight unless verified with a blower door test.
- E. Duct considerations. Many items factor into accurately estimating duct gain and loss. Ensure the actual locations of the supply and return ducts match the load calculation as close as possible. This is critical for allowing your load calculation software to estimate duct loss/gain in to your load.
- F. Review the air flow (CFM) section of your load calculation. As building construction and insulation materials improve, heat loss and heat gain values may be significantly less than the required air flow. Keep in mind, a Waterless Geothermal® system requires 400 CFM of air flow per unit ton for proper operation. It may be necessary to up size equipment when the load calculation air flow requirements are significantly higher than what can be provided at 400 CFM per unit ton. This is typically seen in the cooling side of the load as cooling requires greater air flow then heating. Keep in mind, you must have proper air flow and air exchanges to condition a space. We recommend up sizing the equipment so as to be able to provide at least 75% of the load calculation air flow requirement.

Example: The total cooling load (heat gain) is 36,000 BTUH which is 3 tons of equipment. The load calculation air flow requirement calculated in the load is 2,000 CFM. Keep in mind that if a 3 ton unit is selected based on heat gain alone, you only have 1,200 CFM (400 CFM per ton) which is 800 CFM short. In this example, we would use a multiplier of .75 for the 2,000

CFM given in the load calculation. $2,000 \times .75 = 1,500$ CFM. In this example, you will want to select a 4 ton unit giving you 1,600 CFM.

Load Calculation Don'ts

- A.** Do not design for record-breaking weather conditions. The ASHRAE 99% and 1% tables are sufficient.
- B.** Do not reduce known ceiling, wall or floor R-values "just to be safe."
- C.** Do not use internal load assumptions that cannot be defended.
- D.** Do not add extra occupancy loads for "entertaining groups of people" under normal living conditions to a residential load calculation.
- E.** Do not add extra internal loads for special events.
- F.** Do not use "rules-of-thumb." The idea that the required equipment capacity equals the floor area (square footage) divided by some magic number is absurd, and is not accurate enough to properly design a DX geothermal system. Heat loss and heat gain depends on individual circumstances.
- G.** When replacing equipment, do not use the existing equipment size as the criteria for the size of the replacement equipment. There is a high probability that the existing equipment was not sized correctly.
- H.** Do not ignore error messages generated by your load calculation software.

Please contact Total Green Mfg. at 419-678-2032 with any question regarding these sizing procedures. Along with proper installation of the equipment per Total Green Mfg. installation manuals, sizing is a critical step necessary for an efficient and reliable system.
